Abstract—The analysis of human dental images is a complex and time-consuming task for a dentist, owing to the irregular and inconsistent various teeth's stuctures. Such analysis is required to detect tooth-related issues, anomalies, or alterations in tooth structure. Therefore, automation is crucial for dental image segmentation and inspection to guarantee accurate diagnosis and improved treatment planning. This article presents a thorough examination and analysis of dental image segmentation. It explores around 62 research works done between 2019 and 2023, utilizing several dental imaging modalities. The survey provides comprehensive information on the latest techniques, encompassing several imaging modalities, performance metrics, datasets employed, and the study's objectives.

Keywords—dental image, teeth, systematic mapping study, artificial intelligence, deep learning

#### I. INTRODUCTION

Artificial Intelligence (AI) has currently changed various fields including dental diagnostic imaging. This convergence of technology and healthcare is reshaping the diagnostic capabilities in dentistry. The integration of AI in dental practice is being extensively studied. It is crucial to systematically examine its applications and consequences in diagnostic imaging, as it greatly assists in detecting problems in tooth structures [1]. Dental imagery is crucial for dentists as it greatly aids in the assessment of images for a comprehensive clinical diagnosis and preventative exams of dental structures [2]. Nevertheless, the process of manually reviewing a vast assortment of dental photos can be laborious due to the poor accuracy of visual inspection and tooth structure analysis [3].

The utilization of computerized tools that employ dental imaging modalities can greatly enhance the investigative procedure in most instances [4]. Dental imaging techniques provide valuable information on tooth development, bone architecture, soft tissues, tooth loss, and decay [5]. The classification of dental imaging techniques primarily consists of intra-oral x-rays (periapical, bitewing, panoramic) and the x-rays of extra-oral (CBCT) [6]. The images are commonly utilized in dentistry and their efficiency enhances the accuracy of medical diagnoses [7]. The process of examining dental images includes several stages such as improving the quality of the image, dividing it into different parts, extracting important characteristics, and identifying specific areas. These steps are important for detecting various dental conditions.

Currently, there is a significant surge in the application of deep learning (DL) and machine learning (ML) methods in dentistry diagnostic imaging. ML was a subset of AI and DL was a subset of ML that used a deep neural network [6]. DL frameworks, often referred to as convolutional neural networks (CNNs), are common for analyzing extensive and intricate picture datasets due to their ability to extract various characteristics from hidden layers [8].

Researchers have put forth a multitude of ML methods to enhance the efficiency and the analysis of dental image segmentation [9]. The use of DL and AI techniques has proven to be highly effective in solving complex segmentation problems in different studies [10] & [11]. This suggests that in the future, we can expect a surge of innovative approaches and significant advancements in dental diagnostic imaging, specifically in ML models for semiotic segmentation.

Previous studies have examined different techniques and procedures used in dental diagnostic imaging. The paper by Katsumata [12] categorizes segmentation techniques into two divisions: edge-based and region-based. Nevertheless, there is a lack of discourse regarding the methods employed to improve the quality of dental diagnostic imaging, the specific image databases utilized, and the many modalities employed in this field. In the following study conducted by Rahimi et al. [13], an examination of dental image diagnosis is offered. The

study specifically focuses on the use of a CNN and its ability to accurately diagnose dental conditions. The evaluation primarily compares the CNN's performance against a reference test utilizing ordinary image data. The past surveys have lacked a comprehensive examination of classical image processing, ML, and DL methods.

In this research, we have introduced two novel contributions that were not addressed in the prior surveys: Initially, we conducted a range of research from 2019 to 2023. This represents a significant increase compared to the earlier surveys conducted by Katsumata [12] and Rahimi et al. [13], which had a smaller sample size. Furthermore, approaches based on distinct imaging modalities, such as periapical, panoramic, CBCT, and bitewing are classified. This paper offers a methodical mapping research with the goal of completing a thorough categorization of AI applications in dentistry diagnostic imaging.

#### II. MATERIALS AND METHODS

#### A. Data Sources

The current systematic mapping study was performed in accordance with the principles in the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension (PRISMA) [14]. The search was limited to articles published between 2019 and 2023 and focused on terms related to AI in dentistry, DL, dental diagnostic imaging, and computer-aided diagnostics. The search was performed utilizing the PICO (problem, intervention, comparison, and framework, as depicted in Table 1. Eldawlatly et al. [15] said the fundamental rule in the PICO format is that the title refers to the research question; otherwise, the abstract should be followed by the content. Then, the question should then be formulated in such a way that it is easier to find a specific answer. To attain these goals, the questions are focused and well-articulated in all four components of its "anatomy," the PICO.

TABLE I. DESCRIPTION OF THE PROBLEM, INTERVENTION, COMPARISON, AND OUTCOME (PICO) ELEMENTS

Research Question	Is AI can significantly support the image	
	analysis in dentistry purposes?	
Problem	The patient's diagnostic images include	
	Periapical, Bitewing, Panoramic, CBCT, and	
	color tooth images.	
Intervention	AI-based models for detecting various dental	
	conditions such as teeth detection, dental	
	disease identification, and dental treatment	
	prediction.	
Comparison	Opinions from the experts and standards from	
	references.	
Outcome	Accuracy, sensitivity, specificity, and f1-score	
	as a measurable or predictive outcome.	

#### B. Resources selection

Complete articles were obtained. Both manual and computer methods were utilized to thoroughly examine the journals. At this initial identification stage, the computer method used is Zotero software, but it is still rechecked manually. The data necessary for this evaluation was chosen with two-stage process. During the initial phase, the papers

were chosen based on the relevance of abstracts and their titles to our study subject. The initial search yielded 483 articles that were sufficiently relevant to address the objective of the study. A total of 102 items were eliminated as a result of duplication. Therefore, we obtained 381 articles for the second phase of selection. Subsequently, the subsequent criterion was employed.

#### C. Consideration studies' criteria

#### 1) Criteria for inclusion

- The paper must have a specific focus on AI and should be relevant to the field of dentistry.
- It is necessary to have specific predicted or quantitative results that can be quantified.

#### 2) Criteria for exclusion

- The articles pertaining to non-AI domains.
- The articles comprised solely of abstracts, lacking the whole content.

These criteria reduced the number of papers to 62 research publications that have undergone screening and article selection (Fig. 1). The entirety of the articles was thoroughly read. The years of articles were considered to analyze the advancement of AI trends that have been produced and evolved in the field of dentistry over time.

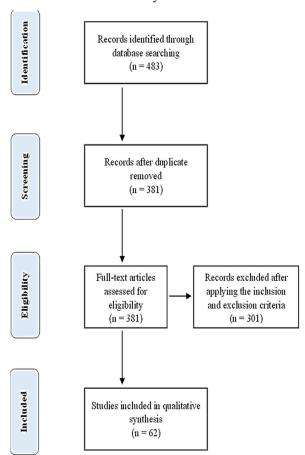

Fig. 1. The preferred reporting items for systematic reviews and meta-analyses extension (PRISMA) procedure was applied in this research.

#### III. RESULTS

The research examined in this systematic review has demonstrated the extensive utilization of AI across many dental disciplines. The majority of the research has employed DL techniques utilizing CNNs such as U-Net, VGG16, InceptionV3, ResNet, YOLO, and others. Several research utilized the geodesic active contour methodology, SVM algorithm, and Fuzzy C-means. Moreover, operations are categorized based on imaging modalities, such as Periapical, Bitewing, CBCT, Panoramic, and color tooth (Fig. 2).

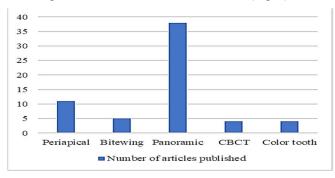

Fig. 2. Articles published based on imaging modalities.

In this research, AI has been employed in 26 studies on teeth detection, 24 studies in dental disease identification, and 12 studies in dental treatment prediction. The dental disease detection comprises 14 studies focused on identifying and diagnosing dental caries, 5 studies aimed at detecting periodontal bone loss, 3 studies dedicated to identifying dental anomalies, 1 study focused on classifying canine impaction, and 1 study focused on detecting apical lesions. The dental predictive treatment includes 5 studies for detecting the mandibular third molar, 2 studies for assessing dental restorations, 1 study for evaluating dental implants, 1 study for identifying dental root canals, 1 study for detecting the dental mental foramen, 1 study for maxillofacial segmentation, and 1 study for classifying dental radiographs. The information may be found in Table 2.

TABLE II. SPECIFICS ON THE RESEARCH THAT HAVE EMPLOYED AI MODELS IN SEVERAL BRANCHES OF DENTISTRY

#### IV. DISCUSSION

AI is revolutionizing the conventional elements of dentistry. AI technologies are frequently employed to develop automated software that optimize the diagnostic and management of data in dentistry [40]. Primarily, they are clinical decision support tools that aid and direct professionals in making more informed judgments. These methods have been employed to improve the accuracy of diagnosis, aid in treatment planning, and forecast the prognosis [43] & [55]. The need for these systems is rapidly increasing due to their efficacy in delivering explanations and logical reasoning [39]. Clinical decision support systems utilizing AI primarily aim to offer expert assistance to healthcare practitioners [38]. Even though AI helps experts, AI also has the challenge of having to consider the practical implications of doctors' decisions, and AI in the world of health, especially dentistry, only helps dentists to take the initial steps in diagnosing, not as the one who takes the final decision to take action. This systematic study examines the application of AI in dentistry, assessing its efficacy in teeth detection, dental disease identification, and dental treatment prediction.

#### A. Application of AI in the Domain of Teeth Detection

Kim et al. [33] utilized AI-based combined CNN to assess the accuracy of teeth identification. The model had a mAP rate of 96.7%, indicating a high level of accuracy, but the data used is still lacking. Tuzoff et al. [38], demonstrated highly comparable outcomes by employing an AI-powered CNN model for tooth recognition, thereafter organizing the findings in a numerical format. The computer-aided diagnostic approach demonstrated an average sensitivity of 0.941 and a precision of 0.9945. The output closely resembled that of an expert but can be further enhanced by augmentation data.

Chen et al. [37], utilized CNN to determine the number of teeth in periapical images and then identify the tooth. The model exhibited exceptional accuracy namely 90% of precision. However, this study did not detect the entire tooth because it used periapical images. The findings demonstrated that AI technologies enhance the convenience of physicians in doing their duties. There is no requirement for them to input the details manually. Dentists can enhance their productivity by inputting their dental charts digitally using automated technologies.

## B. Application of AI in the Domain of Dental Disease Identification

Lee et al. [45] showed that the use of AI, namely R-CNN algorithms, for detecting 17 specific and detailed dental abnormalities on panoramic radiographs yielded good results. The research approach demonstrated a high sensitivity of 0.99. The application exhibited a significantly high level of performance. But model needs to detect anomalies that might be in the early or asymptomatic stages. Lian et al. [50], utilized a DL model specifically created for detecting and locating dental lesions in panoramic images. This study yielded encouraging outcomes that were consistent with previous findings. But changes in pixel intensity due to overlapping skeletal structures, pose significant challenges. Datta et al. [56] utilized periapical images to diagnose dental caries and

demonstrated that the AI-based models performed satisfactorily namely an overall accuracy of 94%, but the proposed method unable to find multiple caries lesions in a single tooth from an x-ray dental image.

Lee, C et al. [44] conducted a study in which they utilized a computer-aided diagnosis system that relied on a sophisticated CNN algorithm. The purpose of this system was to accurately identify and forecast the teeth that were affected by periodontal health issues. The results were satisfactory, with the mean dice similarity coefficient for segmentation exceeding 0.91, but the study image was of poor quality due to overlapping teeth and could not identify vertical defect depth. Moran et al. [2], employed an AI system utilizing CNN to establish a correlation between inadequate periodontal health and systemic health outcomes namely an accuracy of 81.7%, but this study was not able to evaluate the severity of the lesion. Their findings indicate that AI has the potential to facilitate automated diagnosis and serve as a valuable tool for conducting screens for various diseases. Krois et al. [58], employed CNN to identify periodontal bone loss (PBL) based on panoramic dental radiographs and achieved 0.81 accuracy, but it just focused on detecting apical lesions. This device can nonetheless assist in minimizing the dentist's diagnostic endeavors.

### C. Application of AI in the Domain of Dental Treatment Prediction

Precise identification and strategic treatment detection are the important elements for achieving successful dental intervention. AI has been utilized to determine the necessity extractions before commencing dental therapy. Vinayahalingam et al. [66] conducted research where they utilized a CNN model to determine the necessity of identifying and isolating the third molar and inferior alveolar nerve from panoramic radiographs. The outcomes exhibited high promise but the data used was very little. Lee et al. [62] demonstrated a mAP 99% accuracy rate by employing an AI expert system for just identifying mandibular third molars in panoramic radiography images, not maxillary third molars, and possible complications. The findings from both tests indicate that the AI models were successful and accurate in forecasting the necessity for third molar detection. These models serve as a valuable instrument for making informed decisions in clinical practice.

Xu et al. [5] showed a high level of accuracy that proposed an AI model utilizing a SIFT-SVM and CNN for detecting root canal treatment through the analysis of periapical radiographs. The efficacy of root canal therapy mostly hinges on the precision of working length determination. The treatment's prognosis can only be guaranteed when the instrumentation stops at the apical constriction. The findings were comparable to the research conducted by Dasanayaka et al. [9], in which they employed the CNN system to identify the mental foramen, achieving a high DSC rate of 0.987 which can be improved using hyperparameter tuning and an ensemble model.

#### V. CONCLUSION

In recent years, AI applications in dentistry diagnostic imaging have expanded rapidly namely teeth detection [17], dental disease identification [41], and dental treatment prediction [60]. This systematic mapping study offers a thorough examination of this environment. By conducting a thorough examination of the current literature, we have identified significant patterns and prospective changes that define the merging of AI with dentistry practice. The current trend is that AI research in dentistry still uses panoramic images [16], but in the future, CBCT images [8] and color tooth images [54] will be the datasets used in research. In addition, DL models are a method that is increasingly in demand in managing large datasets like CNNs [6].

Research indicates that these AI-driven automated systems shown exceptional performance across a range of different settings. While these results may not surpass those of dentists, they do demonstrate that AI can be deemed suitable for clinical use. These technologies provide significant benefits by strengthening diagnostic accuracy, improving clinical decision-making, and anticipating treatment options, thus enabling physicians to deliver highquality care to their patients [40]. This feature is invaluable as it enables experts to detect instances in the initial stages of tooth diseases [45]. While AI is extensively utilized in several areas of dentistry, certain specializations like pedodontics and oral pathology have yet to fully embrace and implement AI technology. In the future, it can use a DL-based Graphical User Interface (GUI) application that dentists can use without the requirement for programming knowledge [12] and ensure regulatory compliance. Besides that, there are potential drawbacks of AI applications in dentistry, such as the need for large datasets [6] & [60], images of poor quality due to overlapping teeth [44], the risk of algorithmic bias, and the need for human monitoring.

#### ACKNOWLEDGMENT

The authors would like to express their appreciation to the Malaysian Ministry of Higher Education for the financial support of this study through the Fundamental Research Grant Scheme (FRGS/1/2021/ICT02/UTM/02/5). The research is also supported by the Faculty of Computing, Universiti Teknologi Malaysia and Research Center for Artificial Intelligence and Cyber Security, National Research and Innovation Agency (BRIN).
